## ABSTRACT

A relaxor ferroelectric solid solution single crystal is made of a lead-based complex perovskite compound expressed as any of (1-x) Pb  $(Mg_{1/3}Nb_{2/3})$  O<sub>3</sub>·xPbTiO<sub>3</sub>, (1-x) Pb  $(Zn_{1/3}Nb_{2/3})$  O<sub>3</sub>·xPbTiO<sub>3</sub>, and (1-x) Pb $(In_{1/2}Nb_{1/2})$  O<sub>3</sub>·xPbTiO<sub>3</sub>, where a composition ratio x is larger than 0.1 and smaller than 0.2. The relaxor ferroelectric solid solution single crystal is capable of making transitions, at temperatures below the Curie 10 temperature, between a first state which has a high permittivity and blocks optical transmission and a second state which has a low permittivity and allows optical transmission. The relaxor ferroelectric solid solution single crystal undergoes a transition to the second state if an 15 electric field above a threshold is applied thereto in the first state. The relaxor ferroelectric solid solution single crystal undergoes a transition to the first state if heated to or above the Curie temperature in the second state.
